

# Highlights on health in Turkey 2005

Highlights on health give an overview of a country's health status, describing recent data on mortality, morbidity and exposure to key risk factors along with trends over time. The reports link country findings to public health policy considerations developed by the WHO Regional Office for Europe and by other relevant agencies. Highlights on health are developed in collaboration with Member States and do not constitute a formal statistical publication.

Each report also compares a country, when possible, to a reference group. This report uses the 25 countries with low child mortality and low or high adult mortality, designated Eur-B+C by WHO, as the reference group. Eur-B+C comprises Albania, Armenia, Azerbaijan, Belarus, Bosnia and Herzegovina, Bulgaria, Estonia, Georgia, Hungary, Kazakhstan, Kyrgyzstan, Latvia, Lithuania, Poland, Republic of Moldova, Romania, Russian Federation, Serbia and Montenegro, Slovakia, Tajikistan, The former Yugoslav Republic of Macedonia, Turkey, Turkmenistan, Ukraine and Uzbekistan.

To make the comparisons as valid as possible, data, as a rule, are taken from one source to ensure that they have been harmonized in a reasonably consistent way. Unless otherwise noted, the source of data in the reports is the European health for all database of the WHO Regional Office for Europe. Other data and information are referenced accordingly.

## Summary: findings and policy considerations

### Life expectancy

According to WHO estimates, a person born in Turkey in 2003 can expect to live 70 years on average: 73 years if female and 68 years if male. Since 1990, Turks have gained about 4 years life expectancy, significantly more than in other Eur-B+C countries.

As the length of life increases, older people can respond with lifestyle changes that can increase healthy years of life. Correspondingly, health care systems need to shift towards more geriatric care, the prevention and management of chronic diseases and more formal long-term care. Since people are living longer, measures to improve health and prevent disease need to focus on people of working age.

*Ageing and employment policies* (OECD, 2004)

*What are the main risk factors for disability in old age and how can disability be prevented?* (Health Evidence Network, 2003a)

### Infant mortality

In 2003, WHO estimated that 43 out of every 1000 children born in Turkey would die before age 5. The Millennium Development Goal for the under-5 mortality rate for Europe and central Asia is 15 deaths per 1000 live births by 2015 (WHO, 2005). The lowest WHO estimates for the Eur-B+C countries are for Estonia and Slovakia, each at eight deaths per 1000 live births.

Antenatal care is one of the most important services in health care. Nevertheless, it can be expensive, and interventions may be excessive, unneeded and unproven. A simplified model of antenatal care, based on evidence of benefit, is available.

## Selected demographic and socioeconomic information

### Population profile

In mid-2003, the population of Turkey was approximately 71 million, about 66% in urban areas, average for Eur-B+C (WHO, 2005).

In 2003, the percentage of the population 60 and over was 8.2, lower than the Eur-B+C average.

The birth rate in Turkey was 2.4 in 2003, well above the Eur-B+C average. The population increase in Turkey between 1993 and 2003 was 1.6%, the fourth largest in the European Region (WHO, 2005) (Table. Selected demographic indicators).

Selected demographic indicators in Turkey and Eur-B+C,  
2003 or latest available year

Indicators	Turkey	Eur-B+C		
	Value	Average	Minimum	Maximum
Population (in 1000s)	70712.0	–	–	–
0–14 years (%)	37.1	–	–	–
15–64 years (%)	58.7	–	–	–
65+ years (%)	4.2	–	–	–
Urban population (%)	65.8	63.7	25.0	73.3
Live births (per 1000)	20.9	12.8	8.6	27.1
Natural population growth (per 1000)	1.5	0.8	–7.49	23.0
Net migration (per 1000)	0.1	1.8	–6.6	2.1

<sup>a</sup> 2002.

### Socioeconomic indicators

Health outcomes are influenced by various factors that operate at individual, household and community levels. Obvious factors are, for example, diet, health behaviour, access to clean water, sanitation and health services. However, underlying health determinants of a socioeconomic nature also play a role in causing vulnerability to health risks. Here, the key factors are income, education and employment. Though moderately correlated and interdependent, each of these three determinants captures distinctive aspects of the socioeconomic background of a population and they are not interchangeable. Various indicators represent the key socioeconomic determinants of health.

#### ***Income: absolute poverty, relative poverty and income distribution***

There is an income gradient affecting health: the poor generally suffer worse health and die younger than people with higher incomes. For instance, the latter are better able to afford the goods and services that contribute to health, for example, better food and living conditions.

In Turkey, per capita gross national income US\$ 6710 PPP in 2003, slightly below the Eur-B+C average (WHO, 2005) (Figure. Gross national income per person)

<sup>a</sup> The former Yugoslav Republic of Macedonia  
Source: World Bank (2005).

People are considered to be in absolute poverty if their incomes are not sufficient to purchase very minimal goods and services. The World Bank currently uses an absolute poverty line of US\$ 2.15 and US\$ 4.30 income per capita per day to measure poverty in low- and middle-income countries of the WHO European Region (using 1993 international prices adjusted for purchasing power parity). While there is no certainty that the poverty lines measure the same degree of need across countries, the World Bank uses them as a constant to permit comparison. Many countries in the Region calculate their national poverty lines on the basis of a minimum consumption basket selected and priced according to the specific circumstances of the country.

Using the World Bank's recommended benchmarks to measure absolute poverty in Europe, household surveys in Turkey from 1987 to 2000 found the proportion of people living in absolute poverty to be decreasing. The 1987 survey identified 52.4% of the population as living on US\$ 4.30 per day or less, and 15.9% living on US\$ 2.15 per day or less. The latest survey in 2000 found that 39.1% lived on US\$ 4.30 per day and 10.3% on US\$ 2.15 per day (World Bank, 2005).

Relative poverty is an indicator of income level below a given proportion (typically 50%) of the average national income. In high-income countries, there are far more pockets of relative poverty than of absolute poverty.

In 2002, Eurostat reports that 25% of the population in Turkey lived in relative poverty, that is, below the risk-of-poverty threshold set at 60% of the national median equivalized disposable income (after social transfers). That same year, in the nine Eur-B+C countries with data, 16% of the population on average lived in relative poverty. By contrast, in 2001, in the 17 Eur-A countries with comparable data, an average of 14% of people lived in relative poverty (Eurostat, 2005).

Another measure of relative poverty in terms of income is the Gini index. This presents the extent to which the distribution of income (or, in some cases, consumption expenditure) among individuals or

households within an economy deviates from a perfectly equal distribution. A Gini index of 0 represents perfect equality, while an index of 100 implies perfect inequality.

The GINI index for Turkey was 40.4 for 2000. The GINI indices for 15 Eur-B+C countries for 2000 to 2002 range from 26.1 for Bosnia and Herzegovina (2001) to 45.6 in the Russian Federation (2000) (World Bank, 2005).

### **Education**

Education tends to enhance an individual's job opportunities. In so doing, it can improve income, which in turn affects health positively. Education can also give more access to knowledge about healthy behaviour and increase the tendency to seek treatment when needed. A lower level of education – independent of individual income – is correlated with the inability to cope with stress, with depression and hostility and with adverse effects on health.

School enrolment is an indicator of access to education. The secondary school net enrolment represents the percentage of the total population of official school age (defined nationally) that is enrolled in secondary schools.

Per cent net secondary school enrolment data are not available for Turkey. The percentage gross secondary school enrolment (the ratio of total enrolment, regardless of age, to the population of the age group that officially corresponds to secondary education) was 76.0% in 2001. In the neighbouring countries with data for the same year, gross enrolment rates were 86.5% in Armenia and 94.2% in Bulgaria (UNESCO, 2005).

### **Employment**

Being employed tends to be better for health than being unemployed, except in circumstances where employment exposes the individual to physical injury or psychological stress. National unemployment rates and rates for particular sub-populations are monitored to assess the extent to which people have or lack access to opportunities that would enable them to earn an income and feel secure. Vulnerability to health risk is increased by long-term unemployment, that is, continuous periods without work, usually for a year or longer; the socioeconomic status of an individual and of his/her dependents can slide as the period of unemployment increases.

The total unemployment rate in Turkey in 2001 was 8.5%, compared to a Eur-B+C average of 12.9%, keeping in mind that national rates are based on estimates of people available and seeking employment, and that countries have different definitions of labour force and unemployment. In 2002, Turkey's rate increased to 10.6% (ILO, 2005). From 2000 to 2002, 28.5% of those unemployed had been so for a year or longer (World Bank, 2005).

The proportion of Turks 15–24 years old without work but available for and seeking employment was 16.7% in 2001 and 19.5% in 2002. The Eur-B+C average youth unemployment rate for 2001 was 25.2% (ILO, 2005).

---

## Life expectancy (LE) and healthy life expectancy (HALE)

### Life expectancy

According to WHO (WHO, 2005) estimates, a person born in Turkey in 2003 can expect to live 70.0 years on average: 73.0 years if female and 68.0 years if male. Since 1990, Turks have gained about 4 years LE, significantly more than in other Eur-B+C countries.

In addition to LE, it is increasingly important to know the expected length of life spent in good health. WHO uses a relatively new indicator for this purpose – healthy life expectancy (HALE), subtracting estimated years of life spent with illness and disability from estimated LE. For Turkey, WHO (WHO, 2005) estimates that people can expect to be healthy for about 89% of their lives. They lose an average of 8.0 years to illness – the difference between LE and HALE. This loss is higher than the Eur-A average (7.3 years) and the Eur-B+C average (7.6 years).

Since women live longer and since the possibility of deteriorating health increases with age, women lose more healthy years of life (10.2 years) than men (6.8 years). Nevertheless, the longer LE for women in Turkey gives them about one and a half extra years of healthy life. According to WHO estimates for 60 year-olds in Turkey, the HALE for women (14.2 years) is more than three years longer than that for men (12.8 years) (Figure. LE and HALE).

## Mortality

### Infant, neonatal and child mortality

In 2003, WHO estimated that 43 of every 1000 children born in Turkey would die before age 5. The Millennium Development Goal (MDG) for the under-5 mortality for Europe and central Asia is 15 deaths per 1000 live births by 2015. Whether the country will reach the MDG goal by 2015 is hard to predict, as extrapolation of the current WHO estimates is not valid and there are no national data available (WHO, 2005).

The lowest WHO estimates for the Eur-B+C countries are for Estonia and Slovakia, each at 8 deaths per 1000 live births (Figure. Infant deaths and neonatal deaths).

### Maternal mortality

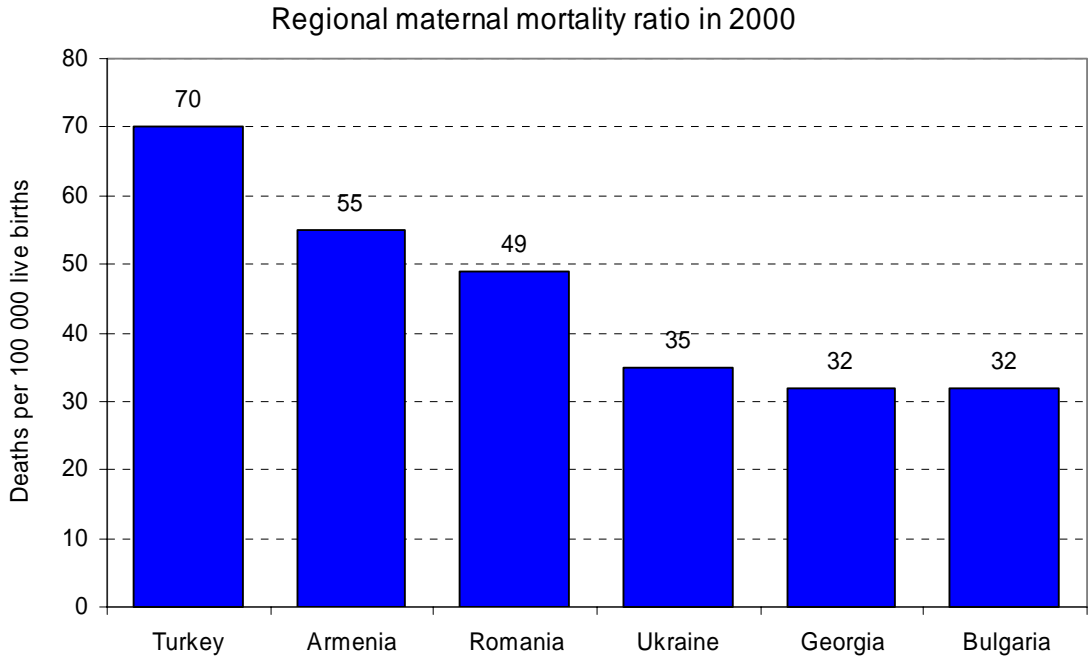

#### Maternal mortality rates (MMR) and the Millennium Development Goal (MDG)

Despite the difficulties in accurately measuring MMR, nationally reported figures are accepted at face value relative to the MDG to improve maternal health – to reduce the MMR by 75% between 1990 and 2015. In some countries, the 2015 target may be equal to or lower than the average current MMR for high income countries in the European Region (the Eur-A 2001 average of five maternal deaths per 100 000

live births). Countries with 2015 targets lower than the current Eur-A average can be judged as having achieved or being likely to achieve the MDG (World Bank, 2004).

However, in some countries, MMR were higher in 2002 than they had been in 1990. Applying the 75% reduction to the 1990 baseline in these countries creates in some cases a 2015 MDG target that requires dramatic reductions in MMR before 2015. In these cases, more important than reaching MMR targets is that countries take concrete action to provide women with access to adequate care during pregnancy and childbirth, initiatives that have proven to bring down MMR.

The latest available WHO-UNICEF-UNFPA estimate of MMR in Turkey is 70 per 100 000 live births for the 2000, above the Eur-B+C average of 56 (UNSD, 2005; WHO, 2005) (Figure. Regional maternal mortality ratio).

## Technical notes

### Calculation of averages

Averages for the reference group, when based on data in the European health for all database of the WHO Regional Office for Europe, are weighted by population. Some countries with insufficient data may be excluded from the calculation of averages. Otherwise, for data from other sources, simple averages have been calculated where required.

To smooth out fluctuations in annual rates caused by small numbers, three-year averages have been used, as appropriate. For example, maternal mortality, usually a small number, has three-year moving averages calculated for all countries. When extreme fluctuations are known to be due to population anomalies, data have been deleted, as appropriate.

### Data sources

To make the comparisons as valid as possible, data for each indicator have, as a rule, been taken from one source to ensure that they have been harmonized in a reasonably consistent way. Unless otherwise noted, the source of data for figures and tables in this report is the January 2005 version of the European health for all database of the WHO Regional Office for Europe. The health for all database acknowledges the various primary sources of the data.

In cases where current census data for national population are unavailable, coupled with ongoing migrations of people in and out of countries, UN estimates or provisional figures supplied by the country are used to approximate national population. Such population figures create uncertainty in standardized death rates.

### Disease coding

Case ascertainment, recording and classification practices (using the ninth and tenth revisions of the International Statistical Classification of Diseases and Related Health Problems: ICD-9 and ICD-10, respectively), along with culture and language, can influence data and therefore comparability across countries.

### Healthy life expectancy (HALE) and disability-adjusted-life-years (DALYs)

HALE and DALYs are summary measures of population health that combine information on mortality and non-fatal health outcomes to represent population health in a single number. They complement mortality indicators by estimating the relative contributions of different causes to overall loss of health in populations.

DALYs are based on cause-of-death information for each WHO region and on regional assessments of the epidemiology of major disabling conditions. The regional estimates have been disaggregated to Member State level for the highlights reports.

National estimates of HALE are based on the life tables for each Member State, population representative sample surveys assessing physical and cognitive disability and general health status, and on detailed information on the epidemiology of major disabling conditions in each country.

More explanation is provided in the statistical annex and explanatory notes of The world health report 2003<sup>1</sup>.

### Limitations of national-level data

National-level averages, particularly when they indicate relatively good positions or trends in health status, as is the case in most developed countries, hide pockets of problems. Unless the health status of a small population is so dramatically different from the norm that it influences a national indicator, health risks and poorer health outcomes for small groups will only become evident through subnational data.

---

<sup>1</sup> WHO (2003). *The world health report 2003 – Shaping the future*. Geneva, World Health Organization (<http://www.who.int/whr/2003/en>, accessed 10 June 2005).

---

### Reference groups for comparison

When possible, international comparisons are used as one means of assessing a country's comparative strengths and weaknesses and to provide a summary assessment of what has been achieved so far and what could be improved in the future. Differences between countries and average values allow the formulation of hypotheses of causation or imply links or remedies that encourage further investigation.

The country groups<sup>1</sup> used for comparison are called reference groups and comprise:

- countries with similar health and socioeconomic trends or development; and/or
- geopolitical groups.

The 27 countries with very low child mortality and very low adult mortality are designated Eur-A by WHO. Eur-A comprises Andorra, Austria, Belgium, Croatia, Cyprus, the Czech Republic, Denmark, Finland, France, Germany, Greece, Iceland, Ireland, Israel, Italy, Luxembourg, Malta, Monaco, the Netherlands, Norway, Portugal, San Marino, Slovenia, Spain, Sweden, Switzerland and the United Kingdom. However, data for most indicators are unavailable for two of the 27 countries: Andorra and Monaco. Therefore, unless otherwise indicated, Eur-A and averages for Eur-A refer to the 25 countries for which data are available.

The 25 countries with low child mortality and low or high adult mortality are designated Eur-B+C by WHO. Eur-B+C comprises Albania, Armenia, Azerbaijan, Belarus, Bosnia and Herzegovina, Bulgaria, Estonia, Georgia, Hungary, Kazakhstan, Kyrgyzstan, Latvia, Lithuania, Poland, Republic of Moldova, Romania, Russian Federation, Serbia and Montenegro, Slovakia, Tajikistan, The former Yugoslav Republic of Macedonia, Turkey, Turkmenistan, Ukraine, and Uzbekistan. Unless otherwise indicated, Eur-B+C and averages for Eur-B+C refer to these countries.

Comparisons should preferably refer to the same point in time, but the countries' latest available data are not all for the same year. This should be kept in mind as a country's position may change when more up-to-date data become available.

Graphs have usually been used to show time trends from 1980 onwards. These graphs present the trends for all the reference countries as appropriate. Only the country in focus and the group average are highlighted and identified in the legend. This enables the country's trends to be followed in relation to those of all the reference countries, and performance in relation to observable clusters and/or the main trend or average to be recognized more easily.

## Glossary

### **Causes of death**

	<b>ICD-10 code</b>
Cerebrovascular diseases	I60–I69
Chronic liver disease and cirrhosis	K70, K73, K74, K76
Chronic obstructive pulmonary disease	J40–J47
Colon/rectal/anal cancer	C18–C21
Diseases of pulmonary circulation and other heart disease	I26–I51
Falls	W00–W19
Female breast cancer	C50
Ischaemic heart disease	I20–I25
Pneumonia	J12–J18
Prostate cancer	C61
Neuropsychiatric disorders	F00–99, G00–99, H00–95
Road traffic injuries	V02–V04, V09, V12–V14, V19–V79, V82–V87, V89
Self-inflicted (suicide)	X60–X84
Trachea/bronchus/lung cancer	C33–C34
Violence	X85–Y09

### **Technical terminology**

Disability-adjusted life-year (DALY)	The DALY combines in one measure the time lived with disability and the time lost owing to premature mortality. One DALY can be thought of as one lost year of healthy life.
GINI index	The GINI index measures inequality over the entire distribution of income or consumption. A value of 0 represents perfect equality; a value of 100, perfect inequality. Low levels in the WHO European Region range from 23 to 25; high levels range from 35 to 36 <sup>1</sup> .
Healthy life expectancy (HALE)	HALE summarizes total life expectancy into equivalent years of full health by taking account of years lived in less than full health due to diseases and injuries.
Income poverty line (50% of median income)	The percentage of the population living below a specified poverty line: in this case, with less than 50% of median income.
Life expectancy at birth	The average number of years a newborn infant would live if prevailing patterns of mortality at the time of birth were to continue throughout the child's life.
Natural population growth	The birth rate less the death rate.
Neuropsychiatric conditions	Mental, neurological and substance-use disorders.
Population growth	(The birth rate less the death rate) + (immigration less emigration).
Standardized death rate (SDR)	The age-standardized death rate calculated using the direct method: that is, it represents what the crude rate would have been if the population had the same age distribution as the standard European population.
